Remarks (Test)

Antibody titre will depend on the stage of the disease. Antibody usually appears by the end of 1st week, so blood taken earlier may give a negative result. Titre increases steadily till the third/fourth week, after which it declines gradually. # Demonstration of a rise in titre of antibody by testing two or more samples is more meaningful than a single test. If first sample is taken late in disease may not show rise in titre. # Antibodies may be present on account of prior disease, inapparent infections or immunisation. H antibodies persist longer than O antibodies. Serum from an individual immunised with TAB vaccine will generally have antibodies to S.typhi, S.paratyphi A and B, while in case of infection antibodies will be seen only against the infecting species. # Person who have had prior infection or immunisation may develop an ANMANESTIC REACTION during an unrelated fever. This may be differentiated by repetition of the test after a week. The anmanstic reaction show onl pp
